Abstract: Caspian miniature horse is a small horse breed native to Northern Iran. Since, there is a lack of comprehensive data on the gross morphometric and morphologic parameters of cranium as well as mandible in this specie; present work was taken. In this work, the skull and mandibles of the ten clinically health Caspian miniature horse aged between 4-6-year-old was used. Then, a total of 17 head measurements and indices were recorded. The skull length, cranial length, nasal length and cranial width were 47.5 cm, 25.6 cm, 21.9 cm and 16.5 cm respectively. Also, the cranial index was 64.45. The distances from facial crest to the infra-orbital canal and from the latter to the root of the alveolar tooth were 4.72 cm and 7.19 cm, respectively. The length and height of the mandibles were 27.68 cm and 15.5 cm, respectively. The distances from the lateral alveolar root to mental foramen and from the mental foramen to caudal mandibular border were 6.94 cm and 20.74 cm, respectively. The distances from mandibular foramen to the base of mandible as well as from caudal border of mandible to below of the mandibular foramen were 5.79 cm and 5.18 cm, respectively. The distances from the base of mandible to condyloid fossa and from the latter to the maximum height of mandible were 3.2 cm and 12.3 cm, respectively. The distance from caudal border of mandible to mandibular foramen and from the latter to mandibular angle were 4.4 cm and 5.3 cm, respectively. These data as important landmarks are discussed with regard to their application to clinical maneuvers around the head of the Caspian miniature horse such as regional anesthesia during treating head injury and dental extraction.

Key words: Applied Anatomy - Head - Caspian miniature horse - Regional anesthesia

INTRODUCTION

The morphologic and morphometric studies of the head region are not only reflect contributions of genetic and environmental components to individual development and describe genetic and ecophenotypic variation, but also are foundations of the clinical and surgical practices [1, 2]. On the other hand, clinical anatomy is one of the principles of the clinical and surgical practice; because it enables the clinician to visualize details of structures relevant to the case at hand [3, 4]. Similarly, the directions of the cranial nerves and their passages from different foramina in the skull are of clinical importance in regional anesthesia around the head [4, 5].

The skull of the horse has the form of a long, four-sided pyramid, the base of which is caudal. It is convenient; however, to exclude the mandible from present consideration [6]. As a whole, there are a few studies on the equine skull in the literature. For instance, Radinsky [7] studied the ontogeny and phylogeny in horse's skull evolution and demonstrated that when comparing skull length, it is necessary to consider the skull as being composed of two major components; the neurocranium and the sphenoid. Evans and McGreevy [8] considered the conformation of the equine skull and reported that there are significant differences in the morphometric indices of craniums between thoroughbreds, standbreds and Arabians breeds.

Although, Caspian miniature horse is an important horse breed native to Northern Iran, but there is a lack of comprehensive data on the gross morphometric and morphologic parameters of cranium as well as mandible in this specie; therefore, the present work was taken.

MATERIALS AND METHODS

This study involved some morphometric parameters of the mandibles and upper jaws of ten Caspian miniature horse aged between 4-6-year-old without any apparent skeletal disorders. The specimens were brought for dissection purposes in the anatomy laboratory, University of Tehran (Tehran, Iran). The heads were severed at the occipito-atlantal joint and processed in the veterinary anatomy laboratory using the boiling maceration techniques for skeleton preparation that have been reported by Simoens et al. [9]. The main steps in skull skeleton preparing briefly are following:

- On the working day, frozen horse head were allowed to thaw.
- Skin and most of the muscles were separated and eyes were enucleated.
- Heads were heated to over 80°C for at least 1 hour in solution of polycarboxylate and anionic surfactant (detergent) and soap chips.
- Muscles of boiled heads were separated with the aid of forceps and scalpel in running water.
- Further separation of muscles and ligaments from the skulls was done after left in detergent water at least 20-30 minutes.
- Separation of remaining muscles and ligaments from the skull was done after left in 1% sodium hypochlorite solution for at least 24 hours.
- After that, the skulls were left in the above solution, for 48-72 hours with solution, being changed at least twice and clean in running tap water.
- The skulls were then left to dry.

A total of 17 morphometric measurements were done in the upper jaw and mandibles using scale, thread and digital calipers and the results were presented as means±SD in Table 1. These morphometric parameters of the upper and lower jawbones of the Caspian miniature horse’s skulls are defined below and shown in Figs. 1-5.

**Skull Length:** From the dorsal lateral nasal cartilages to the external occipital protuberance; sub-divided into cranial length and nasal length.

**Cranial length.**

**Nasal length.**

**Cranial width.**

**Cranial index:** Cranial width × 100/cranial length.

Fig. 2: Skull of the Caspian miniature horse; lateral view.  
F: Facial crest to infra-orbital canal, G: Infra-orbital canal to root of alveolar tooth.

Fig. 3: Mandible of the Caspian miniature horse; lateral view.  
H: Mandibular length, I: Lateral alveolar root to mental foramen, J: Mental foramen to caudal mandibular border.
**RESULTS**

The skull length, cranial length, nasal length and cranial width of the Caspian miniature horse were 47.5 cm, 25.6 cm, 21.9 cm and 16.5 cm respectively. Also, the cranial index was 64.45 (Figure 1, Table 1). In addition, the distances from facial crest to the infra-orbital canal and from the latter to the root of the alveolar tooth were 4.72 cm and 7.19 cm, respectively. (Figure 2, Table 1).

The length and height of the mandibles of the Caspian miniature horses were 27.68 cm and 15.5 cm, respectively. Furthermore, the distances from the lateral alveolar root to mental foramen and from the mental foramen to caudal mandibular border were 6.94 cm and 20.74 cm, respectively (Figure 3, Table 1). In the current work, the distances from mandibular foramen to the base of mandible as well as from caudal border of mandible to below of the mandibular foramen were 5.79 cm and 5.18 cm, respectively. Also, the distances from the base of mandible to condyloid fossa and from the latter to the maximum height of mandible were 3.2 cm and 12.3 cm, respectively (Figure 4, Table 1). Finally, the distance from caudal border of mandible to mandibular foramen and from the latter to mandibular angle were 4.4 cm and 5.3 cm, respectively (Figure 5, Table 1).
DISCUSSION

Comparatively, the values of skull length, cranial length, nasal length and cranial width of the Caspian miniature horse were relatively different from the results on the thoroughbreds, standardbreds and Arabians breeds. It may be due to the existence of significant differences in the skull's morphometric indices between various horses breeds [8].

In the Caspian miniature horse; the distances from facial crest to the infra-orbital canal and from the latter to the root of the alveolar tooth were 4.72 cm and 7.19 cm, respectively. Since the facial crest is very prominent as a guide for tracking the infra-orbital nerve and necessary for the desensitization of the skin of the upper lip, nostril and face on that side of the level of the foramen [3], therefore; these data are of clinical importance. The injection of local anesthetic agents within the canal via the infra-orbital foramen will also lead to analgesia of the incisor, canine and first two premolars. Furthermore, the infra-orbital foramen is located directly dorsal to the third upper premolar tooth in Caspian miniature horses. This information would provide a major landmark to regional anesthesia involving the infra-orbital nerve in the Caspian miniature horse.

In the present study, the distance from the lateral alveolar root to mental foramen was 6.94 cm. This parameter is a vital guide that will detect the location of the mental nerve for this regional nerve block in the Caspian miniature horse; especially for lower lip anesthesia. The injection of the local anesthetic drugs can be made in the rostral aspect of the mandibular canal through the mental foramen to mandibular nerve block in the mental zone. This will ensure the loss of sensation of the lower incisors, premolar and lower lip on the same side [5] during lower lip trauma, dental extraction and treatment of the tooth injuries.

The mandibular length and height in the Caspian miniature horses (Table 1) were lower than the data obtained for early medieval horses in Poland [11]. Similar results had been reported in the values of the distances between the mandibular foramen to base of mandible, the condyloid fossa to height of mandible and condyloid fossa to the base of the mandible [11].

The caudal border of the mandible to bellow of the mandibular foramen was 5.18 cm in the Caspian miniature horses. In addition, the distance from the caudal border of mandible to the level of mandibular foramen and from the latter to the border of mandibular angle was 4.4 cm and 5.3 cm, respectively. The anesthetic agents must to be injecting on the medial side of the mandible's ramus, thereby; a successful nerve block produces anesthesia of the lower jaw with its teeth and the lower lip. These data are necessary for achieving the regional anesthesia of the mandibular nerve and also have clinical importance for desensitization of all the teeth in lower jaw [5].

To best knowledge of the author, there is no literature data on the morphometric parameters of the head region in the Caspian miniature horse with which comparisons could be made. In conclusion, the morphometric values of the skull and clinical anatomy of the head region of the Caspian miniature horse provide an important baseline for further research in this field. Furthermore, these results are of clinical importance that will aid the regional anesthesia of the various nerves around the head especially during treating head injury and dental extraction.
