# New Iterative Method for Solving Large Sparse Generalized Eigenvalue Problem 

S. Pourjafar, S. Kordrostami and A.H. Refahi Sheikhani

Lahijan Branch, Islamic Azad University, Lahijan, Iran

#### Abstract

The generalized eigenvalue problem $\mathrm{AX}=\lambda \mathrm{BX}$ has special properties when ( $\mathrm{A}, \mathrm{B}$ ) is a symmetric and positive definite pair. In this paper we present a new iterative method for soling large sparse generalized eigenvalue problem based on Krylov subspace process. This method uses three parameters, which are weighted Arnoldi, Inner and outer iterations parameters. In this article those parameters have been optimized to increase the speed of convergence. The method has been tested by some numerical examples.

Key words: Generalized eigenvalue problem . Arnoldi, symmetric . positive definite . weighted FOM

## INTRODUCTION

Iterative methods such as the Lanczos algorithm and the inverse vector algorithm are widely used for solving large matrix generalized eigenvalue problems [3-12].

But these methods require solving a linear system of equations of the original size at each iteration of the process and one can use an iterative method such as weighted Arnoldi [2] to solve the systems.

In this paper we present a new method for computing the P-smallest (largest) eigenvalue of pair (A,B). There are three parameters:

- m, which is from the weighted Arnoldi
- The number of inner iterations
- The number of outer iterations.

We show that there is an important relation between these parameters first and then we optimize them.

## DEFINITIONS

If $\mathrm{X} \in \mathrm{R}^{\mathrm{n}}$ and $\left\|\mathrm{X}_{2}\right\|=1$, then the number

$$
R(X)=\frac{X^{T} A X}{X^{T} B X}
$$

is called the generalized Rayleigh quotient. This quotient is well defined if and only the matrix $B$ is positive definite.

Let D be a diagonal matrix, i.e, $\mathrm{D}=$ diag $\left(d_{1}, d_{2}, \ldots, d_{n}\right)$. If $U, V$ are two vectors of $R^{n}$. We define the D-scalar product of $(\mathrm{U} \cdot \mathrm{V})_{\mathrm{D}}=\mathrm{V}^{t} \mathrm{DU}$. This product is
well defined if and only if matrix D is positive definite, i. $e, d_{i}>0, i=1,2, \ldots, n$. The norm associated with this inner product is the $\mathrm{D}-$ norm $\|\cdot\|_{\mathrm{D}}$ and define by

$$
\|U\|_{D}=\sqrt{(U . U)_{D}}=\sqrt{U^{T} D U} \quad \forall U \in R^{n}
$$

## SOLUTION OF LINEAR SYSTEM AX =b BY WEIGHTED FOM METHOD

Azeddin Essai proposed the weighted FOM method [2] to solve the system. In this method a vector $d=\left(d_{1}, d_{2}, \ldots, d_{n}\right)^{t}$ is chosen such that $\|d\|_{2}=\sqrt{n}$.

The following algorithm describes the weighted Arnoldi process which uses the D-inner product (.,.) to construct a D-orthonormal basis of the krylov subspace

$$
\mathrm{k}_{\mathrm{m}}\left(\mathrm{~A}, \mathrm{r}_{\mathrm{r}}\right)=\operatorname{Span}\left\{\mathrm{r}_{\boldsymbol{r}} \mathrm{Ar}_{0}, \ldots, \mathrm{~A}^{\mathrm{m}-1} \mathrm{r}_{0}\right\}
$$

starting with the vector $\tilde{v}_{1}=\frac{v}{\|v\|_{D}}$, where $x_{0}$ is an initial guess, $\mathrm{r}_{0}=\mathrm{b}-\mathrm{Ax}_{0}$ and $\mathrm{D}=\operatorname{diag}\left(\mathrm{d}_{1}, \mathrm{~d}_{2}, \ldots, \mathrm{~d}_{\mathrm{n}}\right)$.

```
Algorithm 1: Arnoldi process
For \(\mathrm{j}=1, \ldots, \mathrm{~m}\)
    \(\mathrm{w}=\mathrm{A} \tilde{v}_{\mathrm{j}}\)
    For \(\mathrm{i}=1, \ldots, \mathrm{j}\)
        \(\tilde{h}_{\mathrm{ij}}=\left(\mathrm{w}, \tilde{Y}_{\mathrm{i}}\right)_{\mathrm{b}}\)
        \(\mathrm{w}=\mathrm{w}-\tilde{\mathrm{h}}_{\mathrm{ij}} \tilde{\mathrm{r}}_{\mathrm{i}}\)
    End \{for\}
    \(\tilde{h}_{j+1, j}=\|w\|_{D}\) if \(\tilde{h}_{j+1, j}=0\) stop
    \(\tilde{v}_{j+1}=\frac{w}{\hat{\mathrm{~h}}_{\mathrm{j}+1, \mathrm{j}}}\)
End \{for\}
```

Theorem 3.1: The vectors $\tilde{v}_{1}, \tilde{v}_{2}, \ldots, \tilde{v}_{\mathrm{m}}$ produced by the weighted Arnoldi algorithm form a D-orthonormal basis of the subspace

$$
\mathrm{k}_{\mathrm{m}}=\operatorname{span}\left\{\tilde{\mathrm{v}}_{\mathrm{l}}, \mathrm{~A} \tilde{\mathrm{v}}_{1}, \ldots, \mathrm{~A}^{\mathrm{m}-1} \tilde{\mathrm{v}}_{1}\right\}
$$

Proof in [2].
Theorem 3.2: Denote by $\tilde{\mathrm{V}}_{\mathrm{m}}$ a $\mathrm{n} \times \mathrm{m}$ matrix with the column vectors $\tilde{v}_{1}, \tilde{v}_{2}, \ldots, \tilde{v}_{m}$ and by $\tilde{H}_{m}$ a $m \times m$ Hessenberg matrix whose nonzero entries are defined by the algorithm 1 . Then the following relations hold:

$$
\begin{aligned}
& A \tilde{V}_{\mathrm{m}}=\tilde{\mathrm{V}}_{\mathrm{m}} \tilde{\mathrm{H}}_{\mathrm{m}}+\tilde{\mathrm{h}}_{\mathrm{m}+1, \mathrm{~m}} \tilde{\mathrm{~V}}_{\mathrm{m}+1} \mathrm{e}_{\mathrm{m}}^{\mathrm{t}} \\
& \tilde{\mathrm{~V}}_{\mathrm{m}}^{\mathrm{t}} \mathrm{D} \tilde{\mathrm{~V}}_{\mathrm{m}} \cong \tilde{\mathrm{H}}_{\mathrm{m}}
\end{aligned}
$$

Proof in [2].
Like all krylov methods, the $\mathrm{m}^{\mathrm{th}}(\mathrm{m} \geq 1)$ iterate $\mathrm{x}_{\mathrm{n}}$ of the weighted FOM belong to the affine krylov subspace $\mathrm{x}_{0}+\mathrm{k}_{\mathrm{m}}\left(\mathrm{A}, \mathrm{r}_{0}\right)$.

The iterate $\mathrm{x}_{\mathrm{m}}^{\mathrm{WF}}$ of the weighted-FOM method is chosen such as its residual is Dorthogonal to the subspace $\mathrm{k}_{\mathrm{m}}\left(\mathrm{A}, \mathrm{r}_{0}\right)$. That is

$$
\mathrm{r}_{\mathrm{m}}^{\mathrm{WF}} \perp_{\mathrm{D}} \mathrm{k}_{\mathrm{m}}(\mathrm{~A}, \mathrm{f})
$$

In this method we use the D-inner product and the D-norm, so, in order to compute the solution in the affine subspace $x_{0}+k_{m}\left(A, r_{0}\right)$, we construct a $D$ orthonormal basis of the krylov subspace $\mathrm{k}_{\mathrm{m}}\left(\mathrm{A}, \mathrm{r}_{0}\right)$ by the weighted Arnoldi process.

An iterate $\mathrm{x}_{\mathrm{n}}$ of this methods can be written as $\mathrm{x}_{\mathrm{m}}=\mathrm{x}_{0}+\tilde{V}_{\mathrm{m}} \mathrm{y}_{\mathrm{m}}$ where $\mathrm{y}_{\mathrm{m}} \in \mathrm{R}^{\mathrm{m}}$.

Therefore, the corresponding residual $\mathfrak{r}_{\mathrm{m}}=\mathrm{b}-\mathrm{Ax} \mathrm{x}_{\mathrm{m}}$ satisfies

$$
\begin{aligned}
\mathrm{r}_{\mathrm{m}} & =\mathrm{b}-\mathrm{A}\left(\mathrm{x}_{0}+\tilde{\mathrm{V}}_{\mathrm{m}} \mathrm{y}_{\mathrm{m}}\right) \\
& =\mathrm{r}_{0}-A \tilde{\mathrm{~V}}_{\mathrm{m}} \mathrm{y}_{\mathrm{m}} \\
& =\tilde{\mathrm{V}}_{\mathrm{m}+1}\left(\tilde{\beta} \mathrm{e}_{1}-\tilde{\tilde{H}}_{\mathrm{m}}\right)
\end{aligned}
$$

Where $\tilde{\beta}=\left\|r_{0}\right\|_{D}$ and $e_{1}$ is the first vector of the canonical basis and $\overline{\tilde{H}}=\binom{\tilde{H}_{m}}{\tilde{h}_{m+1, m} e_{m}^{T}}$.

Then, the weighted-FOM method consists in finding the vector $\mathrm{y}_{\mathrm{m}}^{\mathrm{WF}}$ solution of the problem $\tilde{\mathrm{H}}_{\mathrm{m}} \mathrm{y}_{\mathrm{m}}^{\mathrm{WF}}=\tilde{\beta} \mathrm{e}_{1}$.

[^0]1. Start: Choose $x_{0}, m$ and a tolerance $\varepsilon$, compute $\mathrm{r}_{0}=\mathrm{b}-\mathrm{Ax}_{0}$.
2. Choose the vector $d$ such that $\|d\|_{2}=\sqrt{n}$.
3. Compute $\tilde{\beta}=\left\|r_{0}\right\|_{D}$ and $\tilde{v}_{1}=\frac{r_{0}}{\tilde{\beta}}$.
4. Construct the D-orthonormal basis $\tilde{V}_{\mathrm{m}}$ by the weighted Arnoldi process, starting with the vector $\tilde{v}_{1}$.
5. Solve the system $\tilde{H}_{m} Y_{m}=\tilde{\beta} e_{1}$ by the $Q R$ factorization of $\tilde{H}_{m}$ and set $x_{m}=x_{0}+\tilde{V}_{m} Y_{m}$, $\mathrm{r}_{\mathrm{m}}=\mathrm{b}-\mathrm{Ax}_{\mathrm{m}}$.
6. If $\left\|\mathrm{r}_{\mathrm{m}}\right\|_{2} \leq \varepsilon$ stop

Else set $\mathrm{x}_{0}=\mathrm{x}_{\mathrm{m}}, \mathrm{r}_{0}=\mathrm{r}_{\mathrm{m}}$ and go to 2 .

## INVERSE VECTOR ITERATION METHOD

Let $A$ and $B$ are two $n \times n$ symmetric positive definite matrices, in this method the basic idea is to minimize Rayleigh quotient and to find the smallest (largest) generalized eigenvalue of pair ( $\mathrm{A}, \mathrm{B}$ ).
The algorithm is:
Algorithm 3: Inverse vector iteration process.
Input: Initial vector $\mathrm{X}_{1}$ and tolerance $\varepsilon$
$\lambda_{1}=\frac{\mathrm{X}_{1}^{\mathrm{T}} \mathrm{AX}_{1}}{\mathrm{X}_{1}^{\mathrm{T}} \mathrm{BX}}$
for $\mathrm{j}=1,2, \ldots$ do
solve $A \tilde{X}_{j+1}=B X_{j}$
$\lambda_{j+1}=\frac{\tilde{X}_{j+1}^{\mathrm{T}} A \tilde{X}_{j+1}}{\tilde{X}_{j+1}^{\mathrm{T}} B \tilde{X}_{j+1}}=\frac{\tilde{X}_{j+1}^{\mathrm{T}} B X_{j}}{\tilde{X}_{j+1}^{\mathrm{T}} B \tilde{X}_{j+1}}$
if $\frac{\left|\lambda_{j+1}-\lambda_{\mathrm{j}}\right|}{\left|\lambda_{\mathrm{j}+1}\right|}<\varepsilon$ stop
else $X_{j+1}=\frac{\tilde{X}_{j+1}}{\left(\tilde{X}_{j+1}^{\mathrm{T}} \mathrm{B} \tilde{X}_{j+1}\right)^{1 / 2}} \quad$ (4.1) end $\{$ for $\}$
Theorem 4.1: Let $\lambda_{1}<\lambda_{2} \leq \ldots \leq \lambda_{n}$, where $\lambda_{i}, i=1,2, \ldots, n$ are generalized eigenvalues of symmetric positive definite pair ( $\mathrm{A}, \mathrm{B}$ ) and $\mathrm{X}_{1}<\mathrm{X}_{2}, \ldots, \mathrm{X}_{\mathrm{n}}$ are corresponding eigenvectors, then for any initial vector $X_{1}$ Algorithm 3 converges to the smallest generalized eigenvalue of pair $(A, B)$ and corresponding eigenvector.
Proof in [1]

## Computational remarks:

1) The relation (4.1) in Algorithm 3 guarantees that new eigenvectors are also B-orthonormal i.e, $X_{j+1}^{\mathrm{T}} \mathrm{BX}_{\mathrm{j}+1}=1$ and this helps the implementation of
the numerical process but doesn't help the convergence.
2) The main step in this method is to solve $A \tilde{X}_{j+1}=B X_{j}$, so in this work we try to present a method based on krylov subspace for solving the system.

## THEOREMS

Theorem 5.1: The symmetric definite generalized eigenvalue problem has real eigenvalues and linearly independent eigenvectors.
Proof in [1]
Theorem 5.2: The generalized eigenvectors of pair $(\mathrm{A}, \mathrm{B})$ are B -orthonormal.
Proof in [1]
Theorem 5.3: Let $\lambda_{1}, \lambda_{2}, \ldots, \lambda_{\mathrm{n}}$ are $n$ generalized eigenvalues of symmetric positive definite generalized eigenvalue problem, $A X=\lambda B X$ and $X_{1}<X_{2}, \ldots, X_{n}$ are corresponding generalized eigenvectors and let $\lambda_{1}<\lambda_{2} \leq \ldots \leq \lambda_{n}$, then
i) For any vector $X$ we have; $\lambda_{1} \leq R(X) \leq \lambda_{n}$
ii) If the vector $X$ is closed to eigenvector $X$ then $\mathrm{R}(\mathrm{X})$ has constant value.

## Proof

i) Let X be an arbitrary vector, then by theorem 5.1 we have: $\mathrm{X}=\mathrm{C}_{1} \mathrm{X}_{1}+\ldots+\mathrm{C}_{\mathrm{n}} \mathrm{X}_{\mathrm{n}}$. Now from theorem 5.2 and noting that $\lambda_{i}$ is an eigenvalue of $(A, B)$ and $X_{i}$ is corresponding eigenvector we can write:

$$
\begin{align*}
\mathrm{R}(\mathrm{X}) & =\frac{\mathrm{X}^{\mathrm{T}} \mathrm{AX}}{\mathrm{X}^{\mathrm{T}} \mathrm{BX}}=\frac{\mathrm{C}_{1}^{2} \lambda_{1}+\mathrm{C}_{2}^{2} \lambda_{2}+\cdots+\mathrm{C}_{\mathrm{n}}^{2} \lambda_{\mathrm{n}}}{\mathrm{C}_{1}^{2}+\mathrm{C}_{2}^{2}+\cdots+\mathrm{C}_{\mathrm{n}}^{2}} \\
& =\frac{\lambda_{1}\left(\mathrm{C}_{1}^{2}+\mathrm{C}_{2}^{2} \frac{\lambda_{2}}{\lambda_{1}}+\cdots+\mathrm{C}_{\mathrm{n}}^{2} \frac{\lambda_{\mathrm{n}}}{\lambda_{1}}\right)}{\mathrm{C}_{1}^{2}+\mathrm{C}_{2}^{2}+\cdots+\mathrm{C}_{\mathrm{n}}^{2}} \tag{5.1}
\end{align*}
$$

Since

$$
\mathrm{C}_{1}^{2}+\mathrm{C}_{2}^{2} \frac{\lambda_{2}}{\lambda_{1}}+\cdots+\mathrm{C}_{\mathrm{n}}^{2} \frac{\lambda_{\mathrm{n}}}{\lambda_{1}} \geq \mathrm{C}_{1}^{2}+\mathrm{C}_{2}^{2}+\cdots+\mathrm{C}_{\mathrm{n}}^{2}
$$

then $R(X) \geq \lambda_{1}$ and similarly we can show $R(X) \leq \lambda_{n}$
ii) By (5.1) we have

$$
\mathrm{R}(\mathrm{X})=\frac{\mathrm{C}_{\mathrm{r}}^{2} \lambda_{\mathrm{r}}+\mathrm{C}_{\mathrm{r}}^{2} \sum_{\substack{\mathrm{i}=1 \\ i \neq \mathrm{r}}}^{\mathrm{n}}\left(\frac{\mathrm{C}_{\mathrm{i}}}{\mathrm{C}_{\mathrm{r}}}\right)^{2} \lambda_{\mathrm{i}}}{\mathrm{C}_{\mathrm{r}}^{2}+\mathrm{C}_{\mathrm{r}}^{2} \sum_{\substack{\mathrm{i}=1 \\ \mathrm{i}=\mathrm{r}}}^{\mathrm{n}}\left(\frac{\mathrm{C}_{\mathrm{i}}}{\mathrm{C}_{\mathrm{r}}}\right)^{2}}=\frac{\lambda_{\mathrm{r}}+\sum_{\substack{\mathrm{i}=1 \\ \mathrm{i} \neq \mathrm{r}}}^{\mathrm{n}}\left(\frac{\mathrm{C}_{\mathrm{i}}}{\mathrm{C}_{\mathrm{r}}}\right)^{2} \lambda_{\mathrm{r}}}{1+\sum_{\substack{\mathrm{i}=1 \\ i \neq \mathrm{r}}}^{\mathrm{C}}\left(\frac{\mathrm{C}_{\mathrm{i}}}{\mathrm{C}_{\mathrm{r}}}\right)^{2}}
$$

If $X$ close to $X$ then $C \gg C_{i}, i=1,2, \ldots, n, \dot{\neq r}$ so $\left|\frac{C_{i}}{C_{r}}\right|$ is a very small number, $(i \neq r)$
therefore

$$
1-\left[\sum_{\substack{\mathrm{i}=1 \\ \mathrm{i} \neq \mathrm{r}}}^{\mathrm{n}}\left(\frac{\mathrm{C}_{\mathrm{i}}}{\mathrm{C}_{\mathrm{r}}}\right)^{2}\right]^{2} \cong 1
$$

and we can write

$$
\begin{aligned}
& \mathrm{R}(\mathrm{X}) \cong\left(\lambda_{\mathrm{r}}+\sum_{\substack{\mathrm{i}=1 \\
\mathrm{i} \neq \mathrm{i}}}^{\mathrm{n}} \varepsilon_{\mathrm{i}}^{2} \lambda_{\mathrm{i}}\right)\left(1-\sum_{\substack{\mathrm{i}=1 \\
\mathrm{i} \neq \mathrm{i}}}^{\mathrm{n}} \varepsilon_{\mathrm{i}}^{2}\right) \text { where } \varepsilon_{\mathrm{i}}=\frac{\mathrm{C}_{\mathrm{i}}}{\mathrm{C}_{\mathrm{r}}} \ll 1 \\
& \mathrm{R}(\mathrm{X}) \cong \lambda_{\mathrm{r}}\left(1-\sum_{\substack{\mathrm{i}=1 \\
\mathrm{i} \neq \mathrm{i}}}^{\mathrm{n}} \varepsilon_{\mathrm{i}}^{2}+\sum_{\substack{\mathrm{i}=1 \\
\mathrm{i} \neq \mathrm{F}}}^{\mathrm{n}} \varepsilon_{\mathrm{i}}^{2} \frac{\lambda_{\mathrm{i}}}{\lambda_{\mathrm{r}}}\right) \\
& \cong \lambda_{\mathrm{r}}\left(1+\sum_{\mathrm{i}=1}^{\mathrm{n}}\left(\frac{\lambda_{\mathrm{i}}}{\lambda_{\mathrm{r}}}-1\right) \varepsilon_{\mathrm{i}}^{2}\right) \\
& R(X) \cong \lambda_{r}\left(1+O\left(\varepsilon^{2}\right)\right)
\end{aligned}
$$

## WEIGHTED FOMHINVERSE VECTOR ITERATION METHOD

Now we are prepared to write the main algorithm of this paper, which is a combination of algorithm 2 and 3 , the resulting algorithm is:

Algorithm 4: Weighted FOM-inverse vector iteration method

Input initial vector $\mathrm{x}_{1}$ whit $\left\|\mathrm{x}_{1}\right\|=1$ and tolerance $\varepsilon$ and parameter m .

$$
\begin{aligned}
& \lambda_{1}=\frac{\mathrm{x}_{1}^{\mathrm{T}} \mathrm{Ax}_{1}}{\mathrm{x}_{1}^{\mathrm{T}} \mathrm{Bx}_{1}} \\
& \mathrm{x}_{\mathrm{m}}=\mathrm{x}_{1} \\
& \text { For } \mathrm{k}=1,2, \ldots \text { do } \\
& \quad \text { Compute } \mathrm{r}_{0}=\mathrm{Bx}_{\mathrm{k}}-\mathrm{Ax}_{\mathrm{m}} \\
& \text { For } \mathrm{z}=1,2, \ldots \text { do }
\end{aligned}
$$

Choose the vector $d$ such as $\|d\|_{2}=\sqrt{n}$ and set $\mathrm{D}=\operatorname{diag}(\mathrm{d})$
Compute $\tilde{\beta}=\left\|\mathrm{r}_{0}\right\|_{\mathrm{D}}$ and $\tilde{\mathrm{v}}_{1}=\frac{\mathrm{r}_{0}}{\tilde{\beta}}$
Construct the D-orthonormal basis $\tilde{V}_{m}$ by the weighted Arnoldi process, starting with $\tilde{\mathrm{v}}_{1}$
Solve $\tilde{H}_{m} Y_{m}=\tilde{\beta} e_{1}$ and set $x_{m}=x_{0}+\tilde{V}_{m} Y_{m}$,

$$
\mathrm{r}_{\mathrm{m}}=\mathrm{Bx}_{\mathrm{k}}-\mathrm{Ax}_{\mathrm{m}}
$$

If $\left\|\mathrm{r}_{\mathrm{m}}\right\|_{2}>\varepsilon$ then $\mathrm{x}_{0}=\mathrm{x}_{\mathrm{m}}, \mathrm{r}_{0}=\mathrm{r}_{\mathrm{m}}$
end \{for\}
$\tilde{\mathrm{x}}_{\mathrm{k}+1}=\mathrm{x}_{\mathrm{m}}$
$\lambda_{k+1}=\frac{\tilde{x}_{k+1}^{\mathrm{T}} \mathrm{A} \tilde{\mathrm{x}}_{\mathrm{k}+1}}{\tilde{\mathrm{x}}_{\mathrm{k}+1}^{\mathrm{T}} \mathrm{B}}{ }_{\mathrm{k}+1}$

$$
\begin{aligned}
& \text { If } \frac{\left|\lambda_{k+1}-\lambda_{k}\right|}{\lambda_{k+1}}<\varepsilon \text { then stop } \\
& \text { Else } x_{k+1}=\frac{\tilde{x}_{k+1}}{\left(\tilde{x}_{k+1} B \tilde{x}_{k+1}\right)^{\frac{1}{2}}} \\
& \text { end \{for\} }
\end{aligned}
$$

As algorithm 4 shows, there are 2 loops in this algorithm, one computes the eigenvector and is called outer iteration, the other solves the system of linear equation at each iteration, which is called inner iteration. Numerical tests show that there is a significant relation between parameter m and innerouter iterations.

## NUMERICAL TEST 1

Let A and B are $1000 \times 1000$ matrices as:

We apply algorithm 4 to find the smallest eigenvalue with initial vector $\tilde{v}_{1}$ and the stopping criterion is set as $\varepsilon \leq 10^{-7}$ where $\varepsilon=\frac{\left|\lambda_{\mathrm{k}+1}-\lambda_{\mathrm{k}}\right|}{\lambda_{\mathrm{k}+1}}$.

Number of required inner iterations to achieve a desired accuracy, i.e, $10^{-7}$, for $\mathrm{m}=2,4,6$ are shown in Fig. 1:
We can see that by increasing the value of $m$ the number of outer and inner iterations decrease, therefore the consuming time also decreases. But note that if $m$ is very large then because of loosing orthogonality property. Number of iterations increase.

For example in this example for $m>6$, the number of outer-iterations and inner iteration are constant, therefore the best m in algorithm 4 for this example is $\mathrm{m}=6$ (Table 1 ).

In Fig. 2 the total number of required inner iterations to reach a high accuracy $\varepsilon=10^{-7}$ for $\mathrm{m}=2,4,6$ is shown. We can see that when $m$ increases the amount of iterations decreases.

Fig. 1: Showing number of required inner-iterations to achieve a desired accuracy, for $\mathrm{m}=2,4,6$ (left to right)

Table 1:Shows implementation of Algorithm 4 for pair (A,B) with different value of m and $\varepsilon=10^{-7}$

|  | Inner <br> iteration | Outer <br> iteration | Total inner <br> iteration | Tim |
| :--- | :---: | :---: | :---: | :---: |
| 2 | 30 | 29 | 60 | 53.04 |
| 4 | 10 | 28 | 40 | 18.87 |
| 6 | 6 | 27 | 36 | 12.49 |
| 8 | 6 | 27 | 48 | 24.11 |

Fig. 2: Comparing the total number of inner iterations needed to reach a desired accuracy for $\mathrm{m}=$ $4,6,8,10,12$. By FOM inverse vector iteration method [7] and for $\mathrm{m}=2,4,6$ by W-FOM inverse vector iteration method which can be compared with the W-F-Inverse method

According to Fig. 2, it is noticeable that in the W-F method for $m=6$, we reach a to a limited case and the number of total inner iterations which are needed to gain a desirable accuracy $\left(\varepsilon=10^{-7}\right)$, equals to 36 , but in the F method for $\mathrm{m}=12$ reach to a limited case and the amount of total inner iterations decreases and it equals to 48 . Therefore in W-F method the total number of iterations is much less than the F method.

## DEFLATION

The algorithm we have described finds the smallest eigenvalue. Once it is done, we can go to find the next smallest eigenvalue by the same procedure through deflation. When $P$ eigenpairs have been found, let $V_{P}$ be the matrix consisting of the P eigenvectors with $V_{P}^{T} B V_{P}=I$ and $E_{P}$ be the diagonal matrix consisting of the corresponding eigenvalues. $A V_{P}=B V_{P} E_{P}$. Then we consider

$$
\begin{equation*}
\left(\mathrm{A}_{\mathrm{p}}, \mathrm{~B}\right) \equiv\left(\mathrm{A}+\left(\mathrm{BV} \mathrm{~V}_{\mathrm{P}}\right) \Sigma\left(\mathrm{BV}_{\mathrm{P}}\right)^{\mathrm{T}}, \mathrm{~B}\right) \tag{8.1}
\end{equation*}
$$

where $\Sigma=\operatorname{diag}\left\{\delta_{i}-\lambda_{i}\right\}$ with $\delta_{i}$ any value chosen to greater than $\lambda_{P+2}$. Then it is easy to check that the eigenvalues of (8.1) are the union of $\left\{\lambda_{P+1}, \lambda_{P+2}, \ldots, \lambda_{n}\right\}$

Table 2:Shows implementation of Algorithm4 and deflation for computing 4 smallest eigenvalues of pair $(A, B)$ by $\varepsilon=10^{7}$

|  |  | Inner <br> P | m | -iteration |
| :--- | :---: | :---: | :---: | :---: | :---: | | Outer |
| :--- |
| -iteration | Tim.

and $\left\{\delta_{1}, \ldots, \delta_{p}\right\}$. Thus, it's smallest eigenvalue is $\lambda_{P+1}$ and by applying our method to (8.1), we find $\lambda_{\mathrm{P}+1}$.

Numerical test 2: Let A and B are $1000 \times 1000$ matrix used in numerical test 1 .

By applying algorithm 4 and deflation process we find 4 smallest generalized eigenvalue of pair ( $\mathrm{A}, \mathrm{B}$ ).

The reason why we choose $m=6$ is to find the smallest eigenvalue. It was the most appropriate m, therefore we used this $m$ to find the rest of the eigenvalues. As we can see in Table 2 by increasing P, the amount of the outer-iterations needed to reach an appropriate accuracy increases and this is predictable because in the first step we use sparse matrix but in the other steps after deflation the other matrices $\mathrm{A}, \mathrm{B}$ are not sparse (Fig. 3).

We have also computed four of the smallest eigenvalues of pair ( $\mathrm{A}, \mathrm{B}$ ) with the FOM-inverse vector method which can be compared with the weighted-Fom-inverse iberation method (Table 3).

The comparison of the two methods in calculating four of the smallest eigenvalues of pair ( $\mathrm{A}, \mathrm{B}$ ) with an accuracy of $10^{-7}$. It is noticed that in the weighted-FOM-inverse method the amount of the inner and outer iterations has decreased a lot, therefore the time needed for computations has also decreased.

## COMMENTS AND CONCLUSIONS

1) As we know there are some methods for computing the rest of eigenvalues, for example, shift method but the advantage of this kind of deflation compared to the shift method is that for any $\delta_{1}>\lambda_{P+2}$ ( $\mathrm{i}=1,2, \ldots, \mathrm{P}$ ) the method converges to $(\mathrm{P}+1)^{\text {th }}$ eigenvalue but in the shift method if we don't use an appropriate shift value it might converge to another eigenvalue.
2) To compute the largest eigenvalue of ( $\mathrm{A}, \mathrm{B}$ ), we just need to compute the smallest eigenvalue of $(-$ $A, B)$ and change the sign to obtain the largest eigenvalue of $(\mathrm{A}, \mathrm{B})$.
3) The vector $d$ will be chosen as $d_{i}=\sqrt{n} \frac{\left|\left(r_{i}\right)\right|}{\left\|r_{0}\right\|_{2}}$. Such a choice favors the components of the residual which are far away from zero.

Table 3: Shows the comparison between FOM-Inverse and Weighted-FOM- Inverse methods
