Institute of Chemical Sciences, Centre for Phytomedicine and Medicinal Organic Chemistry, University of Peshawar, Peshawar, KPK, 25120, Pakistan

Abstract: Phytochemical screening is an important step for the isolation of bioactive chemical constituents. *Quercus robur* L. aerial parts have been selected to analyse for bioactive natural products. The phytochemical screening showed the presence of different classes of bioactive secondary metabolites. The *in vitro* antimicrobial activity of hexane, chloroform, ethyl acetate and methanolic fraction of *Q. robur* were evaluated against selected pathogens showing moderate activities against *Escherichia coli, Staphylococcus aureus, Klebsiella pneumonia, Staphylococcus epidermidis and Bacillus subtilis* while antioxidant activity (2,2-diphenyl-1-picrylhydrazyl radical scavenging assay) indicated moderate scavenging activity among the entire fractions.

Key words: Quercus Linn • Phytochemical screening • Antibacterial activity • Antioxidant activity

INTRODUCTION

Medicinal plants are a rich source of producing wide number of chemical constituents in most efficient way and with precious selectivity. According to the World Health Organization more than 80% of the world's people depend on traditional medicine for their primary healthcare needs. The medicinal value of the plants is due to their chemical constituents that bring a definite physiological action on the human body to prevent from the diseases. In our continuing studies on medicinal plants; need to screen a number of medicinal plants for promising biological activity [1]. In the recent years, phytochemicals in fruits and vegetables have received a great deal of attention mainly to prevent human diseases caused by oxidative stress which releases reactive oxygen species involved in a number of disorders such as cardiovascular breakdown, tissue injury, DNA damage and develop such tumor. Several studies suggest that antioxidant could prevent accumulation of these reactive oxygen species and be beneficial for the treatment of these pathologies. Human diets which contain vegetables and fruits reduced risk of a variety of tumors, especially epithelial cancers of respiratory and gastrointestinal tract. The systemic screening of antimicrobial plant extracts represents a continuous effort to explore new biologically active

chemical constituents to act against multi-resistant pathogenic bacteria. As a part of our research studies on plants, one of the well know *Quercus* (Fagaceae) *species is Q. Robur* which has been used for the treatment of various diseases such as haemorrhages, chronic diarrhoea, dysentery and asthma. Certain species of *Quercus* are used for treatment of gonorrhoea, diarrhoea, indigestion, asthma, astringent, anti-diabetic, anti-tremor, local anaesthetic, antipyretic, anti-inflammatory, anti-Parkinson and hepatoprotective [2-4]. The present study deals with preliminary phytochemical screening and biological evaluation of aerial parts of *Q. robur* L.

MATERIALS AND METHODS

Collection of Plant Material: *Quercus robur* aerial parts were collected from Razagram District Dir, Khyber Pakhtunkhwa, Pakistan, during the month of February, 2011. The plant was recognized by Prof. Dr. Abdur Rashid and a voucher specimen (No. R.A 763) was deposited in the herbarium, Department of Botany, University of Peshawar, Peshawar, Pakistan.

Extraction and Fractionation of Plant Material: Shade dried aerial parts of Q. *robur* was successively extracted with methanol (x3). The combined methanolic

Corresponding Athor: Ghias Uddin, Institute of Chemical Sciences; Centre for Phytomedicine and Medicinal Organic Chemistry, University of Peshawar, Peshawar, KPK, 25120, Pakistan.

extract was concentrated under vacuum into thick syrup and fractionated into n-hexane, chloroform and ethyl acetate fractions.

Antimicrobial Assay against Selected Bacterial Strains: Modified agar well diffusion method was adopted to test the antibacterial activity of the fractions with the use of Müller-Hinton agar (MHA) as medium. The cultures were equipped in triplicates at 37°C incubation temperature for a period of 24 to 72 hours. 0.6 ml of the broth culture of the tested organism was put in a sterile Petri-dish and added 20 ml of the sterile molten MHA. Wells were jaded into the medium using 0.2 ml of each fraction while Streptomycin (2 mg/ml) was used as a standard of the antimicrobial agent. Inoculation was done for an hour ensure the diffusion of the antimicrobial agent into the medium. The inoculation plates were incubated for 24 hour at 37°C and the diameters of the zone of inhibition of microbial growth were measured in millimetres.

Antioxidant Activity: The hydrogen atom or electron donation abilities of the corresponding extracts/fractions and standards were measured from the bleaching of the purple-colored methanol solution of 2,2-diphenyl-1picrylhydrazyl (DPPH.) Assay was carried out according to the standard method of Blois [5, 6] with a slight modification. Briefly, a 1 mM stock solution of DPPH radical solution in methanol was prepared and 1 ml of stock solution was mixed with 3 ml of sample solutions in ethanol (containing 20-100 µg) and control (without sample). The resultant mixture was briefly shaken and maintained at room temperature for 30 min. Absorbance was measured spectrophotometrically at 517 nm. Decreasing of the DPPH solution absorbance indicates an increase of the DPPH radical-scavenging activity. Radical scavenging activity (RSA) was expressed as the inhibition percentage and calculated by using the following equation,

RSA
$$\% = [(A-B)/A)] \times 100$$

where,

A = Absorbance of the control solution and
B = Absorbance of the test solution.

Phytochemical Screening: The phytochemical tests were performed to assess the qualitative chemical composition of different fractions of *Q. robur* followed by the standard procedures illustrated by [7-10] for detection of the phytochemicals.

Alkaloids: 0.2 g of each fraction was warmed with 2% H₂SO₄ for two minutes. The reaction mixtures were filtered and added few drops of Dragendroff's reagent to each filtrate. Orange red precipitate indicates the presence of alkaloids moiety.

Tannins: A small quantity of each extract was mixed with water and heated on water bath then filtered. A few drops of ferric chloride were added to each filtrate. A dark green solution indicates the presence of tannins.

Anthraquinones: 0.5 g of each extract was boiled with 10 % HCl for few minutes on water bath. The reaction mixtures were filtered and allowed to cool. Equal volume of CHCl₃ was added to each filtrate and few drops of 10% ammonia was also added to each reaction mixture and heated for few minutes. Rose-pink colour formation indicates the presence of anthraquinones.

Glycosides: Each extract was hydrolyzed with HCl and neutralized with NaOH solution. Few drops of Fehling's solution A and B were added to each mixture. Formation of red precipitate indicates the presence of glycosides.

Reducing Sugars: Each extract was shaken with distilled water and filtered. The filtrates were boiled with few drops of Fehling, s solution A and B for few minutes. An orange red precipitate indicates the presence of reducing sugars.

Saponins: 0.2 g of each extract was shaken with 5 ml of distilled water and heated to boiling. Frothing (appearance of creamy miss of small bubbles) shows the presence of saponins.

Flavonides: 0.2 g of each extract was dissolved in diluted NaOH and few drops of conc. HCl were added. A yellow solution that turns colourless indicates the presence of flavonoids.

Phlobatanins: 0.5 g of each extract was dissolved in distilled water and filtered. The filtrate was boiled with 2 % of HCl solution. Red precipitate shows the presence of phlobatanins.

Steroids: 2 ml of acetic anhydride was added to the mixture of 0.5 g of each extract and conc. H_2SO_4 (2 ml). The colour change from violet to blue or green in some samples indicates the presence of steroids

Terpenoids: 0.2 g of the each extract was mixed with 2 ml of chloroform and conc. H_2SO_4 (3 ml) was carefully added to form a layer. The formation of a reddish brown coloration at the interface indicates positive results for the presence of terpenoids.

RESULTS AND DISCUSSION

The weight percentage yield of n-hexane, chloroform, ethyl acetate and methanol fractions of Q. *robur* aerial plant are shown in Table 1. The ethyl acetate fraction contains a greater proportion by mass of the polar phytoconstituents.

The preliminary phytochemical screening of *Q*. robur fractions showed the presence of bioactive secondary metabolites constituents such as alkaloids, anthraquinones, saponins, tannins and terpenoids (Table-2). The literature revealed that medicinal plants are backbone of traditional medicine and biological activities of the plants extracts/fractions are due to the presence of primary and secondary metabolites which were classified as antimicrobial chemical constitutes. Phenolic chemical constituents such as phenolic acids, flavonoids and tannins are played the major role of antioxidant capacity of plants and biological activities may be related to their antioxidant activity [11] while tannins contributed a major role as antihaemorrhagic, antihyper cholesterol, hypotensive and cardiac depressant agent [12]. Steroids, terpenoids and saponins have analgesic, hypocholesterolemic, anti-diabetic properties [13-15]. The antimicrobial activity of *O. robur* fractions were evaluated for their antibacterial potential against selected bacteria strains; Staphylococcus aureus, Staphylococcus epidermidis, Bacillus subtilis, Escherichia coli and Klebsiella pneumonia (Table 3). Most of the fractions have moderate antimicrobial activity against selected bacteria due to the presence of antimicrobial substances in the plant. Plants derived phytochemicals have significant contribution to human health. Tannins are phenolic substances which is a major group of secondary

metabolites have a potent antioxidants and free radical scavenger which can act as hydrogen donor, reducing agents and singlet oxygen quenchers [16]. Based on the medicinal value and phytochemicals of the plants; antioxidant activity was evaluated of the various fractions of methanolic extract of *Q. Robur* by DPPH radical scavenging assay which showed moderate activity against the standard drug querceitin while chloroform fraction was the least active among all fractions (Figure 1). Further study is needed to isolate, characterize and elucidate of the bioactive components responsible for antimicrobial and antioxidant properties.

CONCLUSIONS

It has been concluded that *Q. robur* contained interesting biological active phytoconstituents which exhibited moderate antimicrobial and antioxidant activity. After toxicological studies on some eventual harmful chemical constituents present in the extracts or their fractions and suggest using plant extract as natural antioxidant and antimicrobial for nutraceutical.
