Abstract: In this paper a numerical solution of steady laminar flow of viscous electrically conducting incompressible fluid, over a semi-infinite inclined plate, which is at prescribed mass flux with heat generation is presented. The numerical solutions using an implicit finite difference scheme known as Keller-box method for velocity, concentration and temperature are found. The effects of various parameters like Schmidt number, magnetic field, heat source, Prandtl number and angle of inclination on the velocity, temperature and concentration, skin friction coefficient and Nusselt number are presented in graphical or tabular form.

INTRODUCTION

It is well known that natural convection heat transfer occurs as a result of temperature differences in an enclosure or near a heated or cooled flat plate. Natural convection along an inclined plate has received less attention than the cases of vertical and horizontal plates. However, this configuration is frequently encountered in engineering devices and in the natural environment. A number of researchers have considered an inclined, semi-infinite flat plate in their research because of its engineering applications. The study of natural convection flow of inclined plate is presented by the authors [Ganesan and Palani [1, 2] and Sparrow and Husar [3]]. Said et al. [4] studied the problem of turbulent natural convection between inclined isothermal plates. Chen [5] presented the analysis to study natural convection flow over a permeable inclined surface with variable wall temperature and concentration. Hossain et al. [6] studied the free convection flow from an isothermal plate inclined at a small angle to the horizontal. Anghel et al. [7] presented a numerical solution of free convection flow past an inclined surface. Bhuvaneswari et al. [8] studied exact analysis of radiation convective flow heat and mass transfer over an inclined plate in a porous medium. Sivasankaran et al. [9] presented a Lie group analysis of natural convection heat and mass transfer in an inclined surface. Shit and Haldar [10] studied MHD flow, heat and mass transfer over an inclined permeable stretching sheet with thermal radiation and Hall Effect.

Natural convection processes involving the combined mechanisms are also encountered in many natural processes, such as evaporation, condensation and agricultural drying and in many industrial applications, such as the curing of plastics, cleaning and chemical processing of materials relevant to the manufacture of printed circuitry, manufacture of pulp-insulated cables, etc. The study of the heat generation or absorption in moving fluids is important with dissociating fluids. Specifically, the effects of heat generation may alter the temperature distribution, consequently affecting the particle deposition rate in nuclear reactors, electronic chips and semiconductor wafers. In fact, the literature is replete with examples of heat transfer in the laminar flow of viscous fluids. For instance, Vajravelu and Hadjinicolaou [11] studied heat transfer characteristics in the laminar boundary-layer of a viscous fluid over a stretching sheet with viscous dissipation or frictional heating and internal heat generation. Kumar [12] investigated heat transfer over a stretching porous sheet subjected to power law heat flux in the presence of a heat source.

In the present work, heat and mass transfer over an isothermal inclined plate which is at a constant concentration gradient in the presence of heat generation is studied. The boundary layer equations are solved numerically using an implicit finite-difference scheme which is the Keller-box method [13, 14]. The effects of Schmidt number, Prandtl Number, heat generation parameter, magnetic field and angle of inclination is studied on velocity, concentration, temperature field, skin friction coefficient and Nusselt number are presented.

MATERIALS AND METHODS

A steady laminar flow of an incompressible viscous electrically conducting fluid past a semi-infinite inclined wall with an acute angle $\phi$ from the vertical and at a constant concentration gradient is considered here. The wall is at a constant temperature $T_w$ which is higher than the ambient temperature $T_\infty$, and at prescribed mass flux. The flow is assumed to be in the $x$-direction, which is taken along the semi-infinite inclined plate and $y$-axis normal to it. A magnetic field of uniform strength $B_0$ is introduced normal to the direction of the flow. In the analysis, we assume that the magnetic Reynolds number is much less than unity so that the induced magnetic field is neglected in comparison to the applied magnetic field. It is also assumed that all fluid properties are constant. Then, under the usual Boussinesq’s and boundary layer approximations, the governing equations of the mass, momentum, energy and concentration for the steady flow can be written as,

$$\frac{\partial v}{\partial y} = 0$$

$$v_\nu \frac{\partial \alpha}{\partial y} = \frac{\partial^2 u}{\partial y^2} + g \beta_T (T - T_\infty) \cos \phi + g \beta_c (c - c_\infty) \cos \phi - \frac{\sigma B_0^2 \nu}{\rho}$$

$$\frac{\partial v}{\partial y} = \frac{\alpha \partial^2 u}{\partial y^2} + \frac{Q}{\rho c_p} (T - T_\infty)$$

$$\frac{\partial c}{\partial y} = D \frac{\partial^2 c}{\partial y^2}$$

with boundary conditions

$$u = v = 0, \quad T = T_\infty, \quad -D \frac{\partial c}{\partial y} = m_c, \quad \text{at} \quad y = 0$$

$$u \to 0, \quad T = T_\infty, \quad c \to c_\infty, \quad \text{as} \quad y \to \infty$$

The equation of continuity (1) with boundary condition (5) changes to:

$$v = -v_w$$

On assuming the non-dimensional variables as follows:

$$Y = \frac{y}{v_w}, \quad U = \frac{u}{u_w}, \quad \theta = \frac{T - T_\infty}{T_w - T_\infty}, \quad C = \frac{c - c_\infty}{m_c \sqrt{\nu/D}}$$

$$G_{\text{f}} = \frac{g \beta_T (T_w - T_\infty) \theta}{u_w v_w^2}, \quad G_c = \frac{g \beta_c m_c \theta^2}{u_w v_w^2 D}, \quad M^2 = \frac{B_0^2 \partial \sigma}{\nu v_w^2}$$

$$\text{Pr} = \frac{\rho \partial c_p}{k}, \quad S = \frac{Q \frac{\partial}{\partial y}}{\rho c_p v_w}, \quad \text{Sc} = \frac{\partial}{D}$$

On using the above non-dimensional parameters, the equations (2) to (4) reduces to:

$$\frac{d^2 U}{dY^2} + \frac{dU}{dY} + G_{\text{f}} \theta + G_c \cos \phi - M^2 U = 0$$

$$\frac{d^2 \theta}{dY^2} + \text{Pr} \frac{d\theta}{dY} + \text{Pr} S \theta = 0$$

$$\frac{d^2 C}{dY^2} + \text{Sc} \frac{dC}{dY} = 0$$

With the corresponding boundary conditions,

$$U = 0, \quad \theta = 1, \quad \frac{dC}{dY} = -1, \quad \text{at} \quad Y = 0$$

$$U \to 0, \quad \theta \to 0, \quad C \to 0, \quad \text{as} \quad Y \to \infty$$

Wall shear stress,

$$\tau_f = \mu \left( \frac{du}{dy} \right)_{y=0}$$

and the skin friction coefficient is defined as,
Eqs. (7), (8), (9), (14) and (15) subject to the boundary conditions (10) are solved numerically using the Keller-box method as described by Cebeci and Bradshaw [13, 14]. A study of the velocity field, temperature field, mass transfer, Nusselt number and skin friction of the steady laminar flow of an incompressible viscous electrically conducting fluid past a semi-infinite inclined wall with constant concentration gradient, has been carried out in the present research. Presented results are verified and found in good agreement as that of Kandasamy and Devi [15] and Ramadan and Chamkha [16].

The effects of Sc on concentration are presented in Fig. 2. Concentration decreases as Sc increases. The reductions in the concentration profiles are accompanied by simultaneous reductions in the concentration boundary layer thickness. Physically, the increase of Sc means decrease of molecular diffusivity (D). That results in decrease of concentration boundary layer. Hence, the concentration of the species is higher for small values of Sc and lower for larger values of Sc.

From Figure 3 it is noticed that, an increase in the magnetic field parameter M or angle of inclination (\(\phi\)) leads to a decrease in the velocity. The application of a transverse magnetic field to an electrically conducting fluid rise to a resistive type force called Lorentz force. This force has the tendency to slow down the motion of the fluid. Velocity attains its high peak for vertical plate, the fluid has higher velocity when the surface is vertical.
than when inclined because of the fact that the buoyancy effect decreases due to gravity components ($g \cos \phi$) as the plate is inclined. It is also interesting to note that the velocity has very good and clear effects of the range $0^\circ - 45^\circ$, (please refer [16]).

Figure 4 shows the effects of Pr on temperature. The increase of Pr results in the decrease of temperature distribution, it is because of the fact that fluid has a thinner thermal boundary-layer with higher values of Pr.

Table 1 and Table 2 represents the coefficients of skin friction and Nusselt number. It has been observed that $C_f$ decreases as Pr or Sc or M or $\phi$ increases. Nusselt number increases with Pr whereas it decrease as S increases.

CONCLUSION

In the present research, the effects of Schmidt number, Prandtl number, heat generation parameter, magnetic field parameter, thermal Grashof number, solutal Grashof number and angle of inclination on velocity, concentration and temperature distributions are obtained which can be interpreted as follows:

The velocity decreases with an increase in magnetic parameter or angle of inclination, concentration decreases with the increase in Schmidt number. The Prandtl number reduces the thermal boundary layer. Shear stress decreases as Prandtl number or Schmidt number or magnetic parameter or angle of inclination increases and Nusselt number increases with Prandtl number and decrease as the heat source parameter increases.
Nomenclature:

\( y \) horizontal coordinate (m) \( c_r \) specific heat (J Kg\(^{-1}\) K\(^{-1}\))

\( u \) axial velocity (m/s) \( Q \) heat generation coefficient (W m\(^{-3}\) K\(^{-1}\))

\( \nu \) transverse velocity (m/s) \( \rho \) density (kg/m\(^3\))

\( T \) temperature of the fluid (K) \( D \) mass diffusion coefficient (m\(^2\) s\(^{-1}\))

\( T_f \) far field temperature (K) \( m_w \) wall mass flux (mol/m\(^2\) s)

\( c \) species concentration (mol/m\(^3\)) \( u_s \) surface velocity (m/s)

\( c_s \) far field concentration (mol/m\(^3\)) \( v_s \) suction velocity (m/s)

\( c_{1-s} \) concentration on the surface (mol/m\(^3\)) \( Gr \) thermal Grashof number

\( \dot{g} \) acceleration due to gravity (m/s\(^2\)) \( M_r \) magnetic field parameter,

\( \beta \) coefficient of thermal expansion (K\(^{-1}\)) \( N \) radiation parameter,

\( \beta_s \) coefficient of concentration expansion (mol/m\(^3\) mol\(^{-1}\)) \( S \) heat generation parameter

\( \phi \) angle of inclination (degree) \( Sc \) Schmidt number

\( \nu \) kinematic viscosity (m\(^2\)/s) \( \beta_c \) thermal diffusivity (m\(^2\)/s)

\( \sigma \) electrical conductivity (S/m) \( \beta_{1-s} \) coefficient of concentration expansion (mol/m\(^3\) mol\(^{-1}\))

\( B \) magnetic field coefficient (T) \( \theta \) dimensionless temperature

\( \lambda \) thermal diffusivity (m\(^2\)/s) \( \theta_{1-s} \) dimensionless species concentration
